

Chapter 07

Synchronization Examples

Classical problems and solutions

Outline

- ◆ Classic Problems of Synchronization
- ◆ Bounded-Buffer Problem
- ◆ Readers and Writers Problem
- ◆ Dining-Philosophers Problem
- ◆ Alternative Approaches

Objectives

- ◆ Explain the bounded-buffer, readers–writers, and dining–philosophers synchronization problems.
- ◆ Describe alternative approaches to solve process synchronization problems.

Classical Problems of Synchronization

- ◆ Classical problems used to test newly-proposed synchronization schemes
 - Bounded-Buffer Problem
 - Readers and Writers Problem
 - Dining-Philosophers Problem

Bounded-Buffer Problem

- ◆ Served as the synchronization primitives:
 - n buffers, each can hold one item
 - Semaphore `mutex` initialized to the value 1
 - Semaphore `full` initialized to the value 0
 - Semaphore `empty` initialized to the value n

Bounded-Buffer Problem

◆ Producer

```
do {  
    ...  
    /* produce an item in next_produced */  
    ...  
    wait(empty);  
    wait(mutex);  
    ...  
    /* add next produced to the buffer */  
    ...  
    signal(mutex);  
    signal(full);  
} while (true);
```

Bounded-Buffer Problem

◆ Consumer

```
do {  
    wait(full);  
    wait(mutex);  
    ...  
    /* remove an item from buffer to next_consumed */  
    ...  
    signal(mutex);  
    signal(empty);  
    ...  
    /* consume the item in next_consumed */  
    ...  
} while (true);
```

Readers-Writers Problem

- ◆ A data set is shared among a number of concurrent processes
 - Readers – only read the data set; they do **not** perform any updates
 - Writers – can both read and write
- ◆ Problem – allow multiple readers to read at one time
 - Only a single writer can access the shared data at a time

Readers-Writers Problem

◆ Shared Data

- Data set
- Semaphore `rw_mutex` initialized to 1
- Semaphore `mutex` initialized to 1
- Integer `read_count` initialized to 0

Readers-Writers Problem

◆ Writer

```
do {  
    wait(rw_mutex);  
    ...  
    /* perform writing */  
    ...  
    signal(rw_mutex);  
} while (true);
```

◆ Reader

```
do {  
    wait(mutex);  
    read_count++;  
    if (read_count == 1)  
        wait(rw_mutex);  
    signal(mutex);  
    ...  
    /* perform reading */  
    ...  
    wait(mutex);  
    read_count--;  
    if (read_count == 0)  
        signal(rw_mutex);  
    signal(mutex);  
} while (true);
```

Readers-Writers Problem Variations

- ◆ Several variations of how readers and writers are considered – all involve some form of priorities
 - The **first** readers–writers problem
 - No reader be kept waiting unless a writer permitted to access.
 - Writer may starve.
 - The **second** readers–writers problem
 - No reader may start reading if a write is waiting to access.
 - Reader may starve.
- ◆ Problem is solved on some systems by kernel providing **reader-writer locks**.
 - Need specifying the mode of lock (read or write)
 - Useful if it is easy to identify read / write operations, or if there are more readers than writers.

Dining-Philosophers Problem

- ◆ Philosophers spend their lives alternating thinking and eating
- ◆ Don't interact with their neighbors, occasionally try to pick up 2 chopsticks (one at a time) to eat from bowl
 - Need both to eat, then release both when done
- ◆ In the case of 5 philosophers
 - Shared data
 - Bowl of rice (data set)
 - Semaphore chopstick [5] initialized to 1

Dining-Philosophers Problem

The Situation of the Dining Philosophers

five philosophers sit at a table, thinking
each has a chopstick to the left and
one to the right, with five chopsticks
total

Dining-Philosophers Problem

The Situation of the Dining Philosophers

if one (1) gets hungry, they reach for the left and right chopsticks, allocating both

Dining-Philosophers Problem

The Situation of the Dining Philosophers

(1) has all of the resources needed to eat, eats, and then releases the chopstick resources

Dining-Philosophers Problem

The Situation of the Dining Philosophers

two or more non-adjacent philosophers can eat at the same time as they do not contend for resources (e.g. 2 and 4)

Dining-Philosophers Problem

The Situation of the Dining Philosophers

they use and then release their chopstick resources

Dining-Philosophers Problem

The Situation of the Dining Philosophers

but two adjacent philosophers trying to eat (e.g. 1 and 2) contend for resources, and only one can eat

Dining-Philosophers Problem

The Situation of the Dining Philosophers

(1) has the resources needed to continue, while (2) must wait for resources to become available

Dining-Philosophers Problem

The Situation of the Dining Philosophers

once the successful philosopher (1) finishes eating, they release resources and the other hungry philosopher (2) can now allocate the resource and eat

Dining-Philosophers Problem

The Situation of the Dining Philosophers

if they all get hungry at once, each reaches with their left hand (for example) for a chopstick

Dining-Philosophers Problem

The Situation of the Dining Philosophers

each grasps the left chopstick, but all the chopsticks are allocated, leaving none free for any philosopher's right hand

no philosopher can make progress, therefore none will eat and release its resources

deadlock

Dining-Philosophers Problem

◆ Solution using Semaphore

□ Shared data

```
semaphore chopstick[5];
```

□ The structure of Philosopher i :

```
do {  
    wait (chopstick[i] );  
    wait (chopstick[ (i + 1) % 5] );  
    // eat  
    signal (chopstick[i] );  
    signal (chopstick[ (i + 1) % 5] );  
    // think  
} while (TRUE);
```

□ What is the problem with this algorithm?

- Deadlock will occur if all five philosophers get their left (or right) chopstick.

Dining-Philosophers Problem

- ◆ Several possible remedies to the deadlock problem.
 - Allow at most four philosophers sit at one time
 - Allow a philosopher to pick up her chopsticks only if both chopsticks are available
 - Asymmetric solution
 - Odd-number philosopher first gets left chopstick, while even-number philosopher first gets right chopstick.
- ◆ Must also prevent from starvation
 - Deadlock-free \neq non-starvation

Dining-Philosophers Problem

◆ Solution using Monitor

- ❑ A philosopher may pick up her chopsticks only if both of them are available
- ❑ Distinguish among three states:
enum {THINKING, HUNGRY, EATING} state[5];
- ❑ Philosopher i can eat iff two neighbors are not eating
 - $state[(i+4) \% 5] \neq \text{EATING}$ and $state[(i+1) \% 5] \neq \text{EATING}$
- ❑ Condition variable for delay if hungry but either chopsticks are unavailable.
condition self[5];

◆ Solution using monitor DiningPhilosophers:

```
DiningPhilosophers.pickup(i) ;  
    ...  
    Eat  
    ...  
DiningPhilosophers.putdown(i) ;
```

Dining-Philosophers Problem

□ Definition of monitor DiningPhilosophers:

```
monitor DiningPhilosophers {
    enum {THINKING, HUNGRY, EATING} state[5];
    condition self[5];
    void pickup(int i) {
        state[i] = HUNGRY;
        test(i);
        if (state[i] != EATING)
            self[i].wait();
    }
    void putdown(int i) {
        state[i] = THINKING;
        test((i + 4) % 5);
        test((i + 1) % 5);
    }
    void test(int i) {
        if ((state[(i + 4) % 5] != EATING) &&
            (state[i] == HUNGRY) &&
            (state[(i + 1) % 5] != EATING)) {
            state[i] = EATING;
            self[i].signal();
        }
    }
    initialization code() {
        for (int i ≡ 0; i < 5; i++)
            state[i] = THINKING;
    }
}
```

Alternative Approaches

- ◆ Transactional Memory
- ◆ OpenMP
- ◆ Functional Programming Languages

Transactional Memory

- ◆ A memory transaction is a sequence of read-write operations to memory that are performed atomically.
 - If all operations in a transaction are completed, the memory transaction is committed.
 - Otherwise, the operations must be aborted and rolled back.

```
void update ()
{
    atomic {
        /* modify shared data */
    }
}
```

- ◆ Advantage
 - Transactional memory system responsible for guaranteeing atomicity
 - Transactional memory system can identify which statements in atomic blocks can be executed concurrently

OpenMP

- ◆ OpenMP is a set of compiler directives and API that support parallel programming.

```
void update(int value)
{
    #pragma omp critical
    {
        count += value
    }
}
```

- ◆ The code contained within the `#pragma omp critical` directive is treated as a critical section and performed atomically.

Functional Programming Languages

- ◆ **Functional** programming languages offer a different paradigm than procedural languages in that they do not maintain state.
- ◆ Variables are treated as immutable and cannot change state once they have been assigned a value.
- ◆ There is increasing interest in functional languages such as Erlang and Scala for their approach in handling data races.
